

THE WHOLE-BRAIN CHILD

Revolutionary Strategies to Nurture
Your Child's Developing Mind

Daniel J. Siegel & Tina Payne Bryson

The Big "So What"

When your child melts down or explodes with emotion, it's not about defiance—it's their brain struggling to cope. In *The Whole-Brain Child*, Daniel Siegel and Tina Payne Bryson explain how your child's brain works and develops, how everyday interactions shape that development, and how you can use 12 science-backed strategies to raise calmer, more resilient kids who feel secure, connected, and capable of thriving.

Introduction: What is Whole-Brain Parenting?

Most parenting advice focuses on managing children's behavior. However, lasting change begins with **brain development**—it affects everything from emotional management to decision-making, learning and relationships.

- The brain is constantly changing through experience—a process called **neuroplasticity**. Each time your child laughs, cries, solves a problem, or gets comforted, tiny brain cells called neurons send signals to each other. The more often mental pathways are activated, the stronger the connections grow. Over time, repeated experiences "rewire" the brain, forming default patterns that shape future reactions and behaviors.
- Every interaction you have with your child literally **shapes the architecture of their brain**, thereby shaping their emotions, thinking, and responses for years to come.

The brain isn't a single system. It has **different parts** that handle different jobs:

- The **left brain** is logical and organized;
- The **right brain** is emotional and intuitive;

KEY QUOTES

"In the following pages we explain the whole-brain perspective and give you a variety of strategies to help your children be happier, healthier, and more fully themselves."

"By understanding a few simple and easy-to-master basics about how the brain works, you'll be able to better understand your child, respond more effectively to difficult situations, and build a foundation for social, emotional, and mental health."

"You can use all of the interactions you share—the stressful, angry ones as well as the miraculous, adorable ones—as opportunities to help them become the responsible, caring, capable people you want them to be."

KEY QUOTES

"Integration takes the distinct parts of your brain and helps them work together as a whole."

"Whether you're a parent or other committed caregiver in a child's life, your ultimate goal is to raise kids in a way that lets them thrive."

- The lower brain handles instinctive reactions; and
- The upper brain handles reasoning and empathy.

These parts often operate in conflict, especially when kids are overwhelmed. That's why a child can seem rational one moment and lose control the next. The key to healthy development lies in an **integrated brain**—getting different brain parts to work together.

- Children with well-integrated brains can regulate emotions, make better decisions, build stronger relationships, and thrive academically and socially. Disconnected brains lead to chaotic or rigid behavior, such as tantrums, shutdowns, or defiance.
- Whole-brain parenting facilitates whole-brain integration by:
 - (i) Creating opportunities for the child to engage different parts of their brain; and
 - (ii) Helping those parts to connect and work in harmony.
- In this summary we'll present these concepts in 2 parts:
 - (i) Integrating the Different Parts of the Brain; and
 - (ii) Developing Mindsight

Part 1: Integrating the Different Parts of the Brain

There are 4 parts of the brain that must be integrated for a child to thrive: the left and right hemispheres and the top and bottom brain.

Horizontal Integration: Left and Right Brain

The brain has **2 hemispheres**, each with distinct roles:

- The left brain is logical, literal, and linear. It focuses on order, language, and cause-effect reasoning.
- The right brain is emotional, holistic, and nonverbal. It processes feelings, images, memories, and nonverbal cues such as facial expressions, body language, and tone of voice.

"Whether you're a parent or other committed caregiver in a child's life, your ultimate goal is to raise kids in a way that lets them thrive."

KEY QUOTES

"By helping our kids connect left and right, we give them a better chance of avoiding the banks of chaos and rigidity, and of living in the flexible current of mental health and happiness."

"An emotional desert, where feelings and the right brain are ignored or denied, is no healthier than a flood."

"Using only the right or left brain would be like trying to swim using only one arm."

"When a child is upset, logic often won't work until we have responded to the right brain's emotional needs."

"No matter how nonsensical and frustrating our child's feelings may seem to us, they are real and important to our child. It's vital that we treat them as such in our response."

- Young children (especially those <3 years old) are right-brain dominant—they live in the present moment and often express themselves through emotions, not logic. As they grow and start asking "Why?" questions, it's a sign that their left brain is developing—because the left brain likes to understand how things work and to use language to express that logic.

For kids to thrive, both sides of their brain must work together—a process called **horizontal integration**. This is facilitated by the corpus callosum, a bundle of fibers connecting the two sides of the brain.

- When integration is weak:
 - Right-brain dominance can lead to emotional flooding, such as chaotic meltdowns, anxiety, or irrational behavior.
 - Left-brain dominance can lead to emotional suppression. Kids may take things too literally, shut down, or claim "I don't care" even when they clearly do.
- There are 2 whole-brain strategies for horizontal integration:
 - (i) Connect emotionally, then guide rationally; and
 - (ii) Name emotions to tame them.

Connect emotionally, then guide rationally. When kids are emotionally overwhelmed, their right brain takes over and their left brain is temporarily "offline." In this state, logical reasoning won't work, and harsh demands can make things worse.

- Instead, start with emotional attunement. Engage the right brain using (i) empathy (e.g. "That sounds really frustrating") and (ii) non-verbal cues (e.g. eye contact, a calm tone, gentle touches). Help the child feel safe and understood.
- Once they're calm and the left brain is back online, you can move to logic, problem-solving, or setting boundaries.
- For example, if your child is upset about a sibling getting better treatment, don't start with a logical explanation about fairness. Instead, validate their feelings, e.g. "It feels unfair sometimes, doesn't it?" Form a right-to-right connection, calm them down, then move into logic.

- Similarly, if a child is dysregulated due to hunger, exhaustion or overstimulation, soothe and settle them first before trying to discipline or reason with them.

Name emotions to tame them. When children are scared or upset, their right brain gets flooded with big emotions. Help them to retell the story and put words to those feelings—because this engages their left brain, restores order and helps them make sense of what happened.

- In short, storytelling connects both sides of the brain, helping kids understand their feelings, process difficult experiences, and regain a sense of control.
- For example, 9-year-old Bella developed a fear of flushing the toilet after it overflowed. Her father helped her retell the story, including what happened and how she felt. With each retelling, the fear lost its grip, and she eventually overcame it.
- Here are several tips to help your child re-tell their story:
 - (i) You can start the first line, then let them fill in the details.
 - (ii) Let them lead the storytelling, using simple questions to help them piece together events and name their emotions.
 - (iii) If they're not ready to talk, give them space to relax or encourage them to express themselves by drawing or playing. Avoid direct interrogation as they may simply shut down.

Horizontal integration applies to parents too. Right-brain dominant parents may overreact emotionally, while left-brain dominant parents may become overly rigid and miss emotional connections. Parents with integrated brains can **role-model** how to respond with both empathy and structure, setting boundaries while staying emotionally connected.

Vertical Integration: Top and Bottom Brain

To thrive, kids also need integration between the **top and bottom parts of the brain**. Think of the brain like a two-story house:

- The downstairs brain includes the brain stem and limbic system. It controls basic survival functions (e.g. breathing,

KEY QUOTES

"Reject their generic claims, incidental complaints, and fluffy promises. Instead, anchor them toward the life they already lead and the actions they're already taking."

"Don't underestimate the power of a story to hold a child's attention."

"Integrating and cultivating your own brain is one of the most loving and generous gifts you can give your children."

"Integration allows for a free flow between the lower and higher parts of our brain. It helps build the stairway, so that all the different parts of our brain can be coordinated and work together as a whole."

reflexes), instincts (e.g. fight, flight, or freeze), and strong emotions. It reacts instantly to perceived threats.

- The upstairs brain, mainly the cerebral cortex, handles more complex skills like decision-making, planning, empathy, self-awareness, and emotional regulation. However, when a child is overwhelmed, the downstairs brain can hijack the upstairs brain. It's like a baby gate slamming shut, cutting off access to the upstairs brain, leaving children stuck in emotional reactivity.

Not all tantrums are the same.

- An upstairs tantrum is calculated and intentional, like a child who screams to get a toy in a store, but stops instantly when presented with consequences. In this case, you should stay calm, acknowledge their feelings, but enforce clear limits, e.g., "I know you want the toy, but it's not okay to scream. If you don't stop, we will go home."
- A downstairs tantrum comes from true emotional overwhelm, like a toddler struggling in the bath out of fear of getting water in their eyes. Here, you should sooth the child first. Help them calm down, then gently talk about their behavior. For example: "I know you were upset about the water. But it's not ok to hit others. Next time, say, "I don't like that. Please stop."

For kids to manage emotions and make thoughtful choices, the upper and lower brains must be vertically integrated.

- Children struggle with control and reasoning because:
 - (i) The upstairs brain isn't fully developed until their mid-20s.
 - (ii) When the amygdala—the brain's alarm system—detects a threat, it can shut down access to the upstairs brain, leaving the child stuck in a reactive state.
- There are 3 whole-brain strategies for vertical integration:
 - (i) Engage the thinking brain, not instincts;
 - (ii) Build thinking skills through practice; and
 - (iii) Use movement to calm the brain.

KEY QUOTES

"A child whose upstairs brain is properly functioning will demonstrate some of the most important characteristics of a mature and healthy human being."

"A parent who recognizes an upstairs tantrum is left with one clear response: never negotiate with a terrorist."

"Whereas a child throwing an upstairs tantrum needs a parent to quickly set firm boundaries, an appropriate response to a downstairs tantrum is much more nurturing and comforting."

"A parent's goal should be to help build and reinforce the metaphorical stairway that connects the child's upper and lower brain so that the two can work as a team."

Engage the thinking brain, not the instincts. When a child misbehaves, how you react matters.

- Commands or ultimatums can enrage the downstairs brain to trigger more reactivity. Instead, engage the upstairs brain by offering choices, asking questions, or guiding them in problem-solving.
- Rather than say, "No dessert and that's final!" try saying, "You can have 1 bite of ice-cream if you finish half the pasta first."
- In some situations, there's no room for negotiation. But where possible, guide your child toward thoughtful decision-making.

Build thinking skills through practice. Like muscles, the brain strengthens with use. Encourage kids to use their upstairs brains regularly, to grow their capacity for reasoning, decision-making, and self-control.

- Let them make *age-appropriate choices* (e.g. choose their outfits, manage their schedules) and face the consequences of their choices.
- Teach them self-regulation techniques like deep breathing, counting to 10, or using words to express emotions.
- Ask reflective questions like: "Why do you feel that way?" or "What could you do differently next time?" Encourage activities like journaling or drawing, to help process thoughts or emotions.
- Nurture empathy by helping them to tune in to others' emotions, e.g. "How do you think your friend feels?"
- Promote moral reasoning by discussing ethical dilemmas, e.g. "Is it okay to lie to protect someone?" Model the behavior you want them to learn.

Use movement to calm the brain. Physical movement affects brain chemistry, calms the nervous system, and allows the upstairs brain to come back online.

- When emotions run high, encourage your child to move through play, sports, or physical activities like jumping or biking. Once they reset the body, they'll feel calmer and more focused.

KEY QUOTES

"Every time we say 'Convince me' or 'Come up with a solution that works for both of us,' we give our kids the chance to practice problem solving and decision making."

"The upstairs brain is like a muscle: when it gets used, it develops, gets stronger, and performs better."

"Let your children wrestle with the decision and live with the consequences."

"The more your kids think about what's going on within themselves, the more they will develop the ability to understand and respond to what's going on in the worlds within and around them."

"The next time your children need help calming down or regaining control, look for ways to get them moving."

An amygdala hijack can happen to both kids and adults. **Even the best parents lose control.**

- If you feel yourself reaching a boiling point, stop before you say/do something you regret. Close your mouth, step away and calm down first. Let your child know you need a moment, then breathe, stretch, or move around to regain balance.
- Reconnect and make repairs once you're ready. Apologize if needed, take ownership, and rebuild trust and safety in the relationship.

Memory Integration: Explicit and Implicit

Understand how memory works, so you can help kids to deal with difficult experiences, and make sense of their past in a way that supports emotional well-being.

- Our memories aren't stored as perfect records in mental filing cabinets. Instead, the brain works through associations, linking past and present experiences —often without our awareness
- Each time we recall a memory, we alter it slightly based on our current emotions, beliefs, and context. That's why two people may remember the same event differently.

Memories are stored in **two forms**:

- Implicit memory is unconscious. It influences our feelings and behaviors without us realizing it. For example, a child who had a scary swimming lesson might later feel anxious around pools without knowing why.
 - These memories begin forming even before birth and are shaped by *repeated experiences*.
 - The brain learns to expect familiar patterns—a process called *priming*. For example, if a parent hugs their toddler every day after work, the child's brain learns to expect that hug once the parent returns home.
 - Explicit memory is conscious. It involves facts, events, and experiences we can recall and talk about, such as remembering your first day at school or a family vacation.

KEY QUOTES

"The sooner you repair the connection between yourself and your child, the sooner you can both regain your emotional balance and get back to enjoying your relationship together."

"Your state of mind when you encoded the memory and the state of mind you're in when you recall it influence and change the memory itself. So the story you actually tell is less history and more historical fiction."

"Memories shape our current perceptions by causing us to anticipate what will happen next. Our past absolutely shapes our present and future. And it does so via associations within the brain."

For children to feel emotionally grounded, they need to **integrate implicit and explicit memories**—to understand what happened, how it shaped them, and how to move forward.

- The hippocampus (the brain's "search engine") helps to link implicit memory (emotions and sensations) with explicit memory (facts and narratives), so kids can make sense of their experiences and regulate their emotions.
- If left unintegrated, implicit memories are like scattered puzzle pieces that cause confusing emotions and behaviors. Help kids to piece those parts together into a clear story.
- There are 2 whole-brain strategies for memory integration:
 - (i) Replay memories to process them; and
 - (ii) Practice daily storytelling and recollection.

Replay memories to process them. Help kids to revisit difficult experiences at their own pace. Introduce them to the "mental remote control," where they imagine pausing, rewinding, or fast-forwarding through the memory like a movie.

- This gives them a sense of control over what they recall, reducing fear and anxiety to allow healing. For example, a boy named Eli was traumatized after a woodworking accident. His father helped him retell the story bit by bit, using the mental remote to skip the most painful parts until Eli was ready to face them. Over time, Eli regained his confidence and overcame his fear.

Practice daily storytelling and recollection. Make it a family ritual to talk about everyday events, both the good and the bad. This helps to process hard moments and to reinforce positive experiences, family milestones, and important values.

- Ask guiding questions that encourage recall, e.g. "What happened when you visited your friend?" or "How did you feel when you talked to your teacher?"
- Encourage journaling as a way to express their experiences.
- Use games, old photos, scrapbooks, or keepsakes to spark memories and storytelling. For example, play a game where they share 2 truths and 1 lie, then you guess which 2 are true.

KEY QUOTES

"The more you can help bring those noteworthy moments into their explicit memory—such as family experiences, important friendships, or rites of passage—then the clearer and more influential those experiences will be."

"Just like you might fast-forward through the scary parts of a movie or rewind to watch your favorite scene again, the remote of the mind is a tool that gives your child some control while revisiting an unpleasant memory."

"The more you can help bring those noteworthy moments into their explicit memory... then the clearer and more influential those experiences will be."

Parents are affected by implicit memories too. Unprocessed memories from your past can influence how you react to your child.

- For example, a dad who had buried trauma from a past medical scare found himself panicking every time his baby cried. Only after processing his own memories was he able to respond calmly and appropriately.
- If you find yourself overreacting to your child's behavior, pause and ask yourself: Why am I reacting this way? Does this remind me of something from my past? Once you recognize your triggers, you can consciously choose your response, rather than being driven by automatic reactions.

INTEGRATING PARTS OF THE BRAIN

Horizontal Integration (Left-Right Brain)

Connect emotionally,
then guide rationally

Name emotions to
tame them

Vertical Integration (Top-Bottom Brain)

Engage the thinking
brain, not instincts

Build thinking skills
through practice

Use movement to
calm the brain

Memory Integration (Implicit-Explicit Memory)

Replay memories
to process them

Practice daily
storytelling and
recollection

KEY QUOTES

"By integrating your implicit and explicit memories and shining the light of awareness on difficult moments from your past, you can gain insight into how your past is impacting your relationship with your children."

Part 2: Developing Mindsight

Mindsight is the ability to perceive/shape our inner world, and choose how we respond to them. It includes intrapersonal and interpersonal skills, and requires all 4 parts of the brain to work together.

Intrapersonal Integration (Self-Understanding)

Help kids to connect with their inner world so they can manage emotions, build resilience, and develop a strong sense of self.

- Children often confuse temporary emotions with identity. Instead of saying, "I feel sad," they might say, "I am sad." Instead of, "I made a mistake," they think, "I am a failure." This

"Feelings need to be recognized for what they are: temporary, changing conditions. They are states, not traits."

can be harmful, because passing emotions may harden into deep-seated beliefs about who they are.

One powerful tool for building self-understanding is Daniel Siegel's **Wheel of Awareness**.

- The rim represents things we may focus on (e.g. thoughts, feelings, memories, sensations), while the hub represents awareness or the ability to step back and choose what to focus on.
- One goal of mindsight is to help children return to the hub, rather than getting stuck on any one point of the rim. For example, 11-year-old Josh excelled in school, sports, and music, but constantly felt he wasn't good enough. A therapist helped Josh trace his perfectionism back to early childhood. His brain had linked making mistakes with being abandoned after his father left. Through the Wheel, Josh realized that self-criticism was just one part of his experience, not his whole identity. He learned to shift focus to other parts—like his talents, friendships, and resilience—building new confidence and the ability to enjoy life.
- There are 3 whole-brain strategies for intrapersonal integration:
 - (i) Let fleeting emotions pass;
 - (ii) SIFT the inner landscape; and
 - (iii) Return to the hub of awareness.

Let fleeting emotions pass. Emotions (e.g. sadness or anger) last for only about 90 seconds. The initial surge usually fades quickly, unless they're fueled by ongoing thoughts and reactions.

- Teach kids that emotions are temporary, like passing clouds. Feeling upset doesn't mean they are broken or bad. Help them to notice their emotions without judgment, and let the feelings rise and fall naturally without denying or clinging to them.

SIFT the inner landscape. SIFT stands for sensations, images, feelings, and thoughts—the 4 key elements that shape our inner world.

KEY QUOTES

"We need to help children understand that the clouds of their emotions can (and will) roll on by. They won't feel sad or angry or hurt or lonely forever."

"[Teach] kids that they have choices about what they focus on and where they place their attention."

"We can shift our focus to other rim points on the wheel of awareness, so that we are no longer victims of forces seemingly beyond our control, but active participants in the process of deciding and affecting how we think and feel."

"By directing our attention, we can go from being influenced by factors within and around us to influencing them."

"Simply recognizing different sensations like hunger, tiredness, excitement, and grumpiness can give children a great deal of understanding and ultimately influence over their feelings."

- Sensations: Notice physical body signals (e.g. butterflies in the stomach = anxiety), then use these cues to regulate emotions.
- Images: Help kids to notice mental images from memories, dreams, or imagination, as well as the emotions being triggered.
- Feelings: Use specific words to label emotions (e.g. disappointed, excited), instead of vague labels (e.g. bad, fine).
- Thoughts: Teach them to observe their thoughts and realize that thoughts are not facts. A thought like "I'm so stupid" can be reframed as "I learning from my mistakes."

Return to the hub of awareness. When kids are overwhelmed by strong emotions, they need tools to recenter and calm down. Teach mindsight exercises that help them to return to the hub of awareness, regain balance and control. Examples include:

- Breathing exercises: Guide them to lie down, observe their surroundings, and then focus on their breathing.
- Visualization: Teach them to imagine peaceful scenes, e.g. floating in a pool or swinging in a hammock. When they're overwhelmed, they can use these mental images to relax and regain control.

Parents can also benefit from mindsight. Stay centered in the hub and choose where to focus your attention, so as to better manage your reactions, stay calm, and parent more intentionally.

- Example: Imagine you come home exhausted and see toys scattered all over the floor. You feel irritation rising. But instead of snapping, you pause and remind yourself that feelings are just one point on the rim. You shift your focus to sweeter memories like your child's hugs and laughter. As you redirect your focus, it shifts your emotional state, allowing you to respond in a more thoughtful way.

Interpersonal Integration (Relationship-Building)

Interpersonal integration is about building healthy, meaningful relationships with others, with a balance of individuality and connection. Too much focus on "me" can lead to selfishness and isolation, while too much focus on "we" can lead to dependency and vulnerability to peer pressure.

KEY QUOTES

"When a child becomes aware of the images that are active in his mind, he can use his mindsight to take control of those images and greatly diminish the power they have over him."

"Ideally, we want our kids to recognize that there's a colorful rainbow of rich emotions within them, and to pay attention to these different possibilities."

"Remember that just by talking about the mind, you help develop it."

"To become a part of a well-functioning "we," a person needs also to remain an individual "me.""

- The brain is a social organ that's shaped through interactions with others. Thanks to mirror neurons in our brain, we can understand and mimic others' emotions and actions. We even get infected by others' moods and feelings. That's why yawns are contagious, or why we smile when we see others laugh.
- Through early interactions, children develop essential social skills like listening, reading facial expressions, and sharing. These shape how they approach future friendships, romantic relationships, and even parenting.
 - If caregivers are responsive and nurturing, children learn that relationships are safe, supportive, and comforting. If caregivers are unreliable, distant, or harsh, children may learn to suppress their needs or fear closeness.
- Strong relationships are built on a receptive (open) mindset instead of a reactive (defensive) one:
 - When the brain perceives a threat, it shifts into a defensive fight, flight, or freeze mode, making it harder to listen, trust, or connect.
 - When the brain feels safe, it relaxes and opens up to others, allowing real connection.
- There are 2 whole-brain strategies for interpersonal integration:
 - (i) Build bonds through family fun; and
 - (ii) Turn conflict into connection.

Build bonds through family fun. Positive interactions—whether through games, jokes, or shared activities—strengthen family bonds and teach kids that relationships are a source of happiness and comfort.

- Fun, joyous moments trigger the release of dopamine, a chemical that reinforces positive feelings, thereby strengthening the desire for meaningful relationships.
- Simple ways to bring fun into family life include: games, jokes, surprises, or simple traditions like a Friday movie night or Sunday pancake breakfast.
- Playfulness can also defuse frustration. A well-timed joke or silly gesture can turn tension into laughter.

KEY QUOTES

"Interpersonal integration means that we honor and nurture our different while cultivating our connections with one another."

"Kids who have difficulty relating to others need to have those connections encouraged and cultivated."

"Your state of mind can influence your child's state of mind, letting you transform fussiness and irritability into fun, laughter, and connection."

"Receptivity can lead to resonance—a way of joining from the inside out—that will allow them to enjoy the depth and intimacy that come with meaningful relationships."

"With every fun, enjoyable experience you give your children while they are with the family, you provide them with positive reinforcement about what it means to be in loving relationship with others."

Turn conflict into connection. Conflicts, when handled well, can become opportunities to deepen relationships.

- Use conflicts to teach perspective-taking. Start by validating the child's emotions, even if you disagree with their behavior. Then, guide them to consider the other person's view, e.g. "Do you think he was upset about something?"
- Teach them to read nonverbal cues, like facial expressions, posture, and tone. For example, "Your friend says he's fine, but his shoulders are slumped. How do you think he really feels?"
- Help them express themselves, listen actively, work together to find solutions, and repair relationship ruptures. For example, if a child breaks a sibling's toy, they could fix it, replace it, or do something kind to make amends. Ask, "If your favorite toy were broken, what would help you feel better?"

DEVELOPING MINDSIGHT

Intrapersonal Integration (Self-Understanding)

-  Let fleeting emotions pass
-  SIFT the inner landscape
-  Return to the hub of awareness

Interpersonal Integration (Relationship-Building)

-  Build bonds through family fun
-  Turn conflict into connection

Conclusion and Other Details in the Book

Parenting is a huge responsibility, since every interaction you have with your child shapes their emotional and cognitive development. By applying whole-brain strategies, you can nurture children who are resilient, self-aware, and capable of strong, healthy relationships.

- Remember: parents with integrated brains can better role-model emotional regulation, empathy, and resilience, helping children to learn, grow, and thrive.

KEY QUOTES

"By asking questions about how another person feels, about why someone reacted as he did, we can encourage empathy in our children."

"Even children who don't seem predisposed to connection and compassion can learn what it means to be in relationship, and to fulfill the responsibilities that come with it."

"When you've become the active author of your life story and not merely the passive scribe of history as it unfolds, you can create a life that you love."

- Explain to kids how their brains work. When children understand what's happening inside them, it empowers them to manage their reactions and develop lifelong resilience.

The book includes additional examples, real-life stories, and practical tips to help you apply these strategies across all stages of childhood—from infancy to adolescence. For more details and resources, visit <https://drdansiegel.com/>.

About the Authors

Daniel J. Siegel, M.D. (born 1957) is an acclaimed author, award-winning educator, executive director of the Mindsight Institute, and a clinical professor of psychiatry at the UCLA School of Medicine. He received his medical degree from Harvard Medical School and completed his postgraduate medical education at UCLA. He's the author of several bestselling books, e.g., *Mindsight*, *Brainstorm*, and *The Developing Mind*.

Tina Payne Bryson is a psychotherapist, author, and speaker. She's the Founder/ Executive Director of The Center for Connection, and of The Play Strong Institute, and the co-author of several books. She graduated from Baylor University and earned her Ph.D. from the University of Southern California.

KEY QUOTES
